NAME:

Instructions:

In points 1 and 2, you will be asked to develop a model and a Python script. For the submission of the source code, please create a GitHub repository and add all the source codes used for exploration, training, testing, and the computer vision script. If the trained model artifact is too large and doesn't fit in the repository, kindly deliver it through a Google Drive link. Finally, ensure that the repository contains a README file explaining the content of each source file and specifying which corresponds to each point of the practical test.

1. Natural Language Processing

Based on the Diplomacy dataset (https://sites.google.com/view/qanta/projects/diplomacy?pli=1) train a deep learning model to predict if a message is a lie or not.

- This model must be trained with transfer learning or **free** LLMs using a Python framework.
- The model must be a transformer architecture and **you can't use allenlp library** as it was used on the paper's code.
- Compare the model you trained with the benchmark provided on the ACL'20 paper (Peskov et al.).

Grading Criteria for NLP Task:

- Analysis, EDA, and Explanation (40%):
 - o Perform a thorough analysis prior to tackling the exercise.
 - o Conduct Exploratory Data Analysis (EDA).
 - o Explain your approach in a PowerPoint presentation (ppt).
- Implementation and Documentation (40%):
 - o Diagram the implemented code.
 - o Document the code and explain it in a PowerPoint presentation (ppt).
- Metric Achievement (20%):
 - Achieve a satisfactory metric on the exercise, specifically a score above 0.7.

2. Computer Vision

In the "files" folder, you have two PDF files corresponding to the property certificates of two Colombian real estate properties. Likewise, for each .pdf file, there is a .json file representing the results of applying an OCR model with AWS Textract to the first page of each PDF. These .json files contain the extracted texts and coordinates from each document.

Based on these inputs, the task is to develop a Python code that receives the JSON file route, loads it, and extracts the Registration Number (Nro Matrícula), the print date (in YYYY-MM-DD format), the department, municipality, and locality (vereda) of the certificate or property, as well as the status of the folio. This information should be extracted from the .json file corresponding to the first page of each document.

The code should be singular and generic, meaning it should work for either of the two provided certificates. During the development evaluation, additional certificates will be provided to validate whether the code generalizes well for the extraction logic with other certificates having the same structure and arrangement of the mentioned fields but different values.

For more information on how AWS Textract delivers OCR, you can visit:

https://docs.aws.amazon.com/textract/latest/dg/API_DetectDocumentText.html

Grading Criteria for Computer Vision Task:

- Explanation and Approach (20%):
 - o Provide an explanation on how you approached the exercise.
 - Present your approach in a PowerPoint presentation (ppt).
- Implementation and Documentation (50%):
 - o Document the solution.
 - o Diagram the code.
 - o Explain the solution in a PowerPoint presentation (ppt).
- Result Accuracy (30%):
 - o Achieve satisfactory results with the extraction logic.

3. Programming or SQL:

The following problem can be solved using only SQL, using Python or SQL + Python and you can use the libraries and functions that each tool provides.

For the attached file RUAF.csv there is the following structure:

- The information must be organized horizontally (columns)
- The beginning of the record is identified with "¬-*-¬DATA"
- The information is organized by sections, but these should not remain in the final table
- If the record does not record information, create a field "marca_sin_information" with the indicator 0=with information, 1=without information.
- The fields must be with the snake_case notation
- Valid sections and related fields are as follows:

Sección/Campo
